Query Operations

Relevance Feedback & Query Expansion
Relevance Feedback

- After initial retrieval results are presented, allow the user to provide feedback on the relevance of one or more of the retrieved documents.
- Use this feedback information to reformulate the query.
- Produce new results based on reformulated query.
- Allows more interactive, multi-pass process.
Relevance Feedback Architecture

- **Query String**
- **Document corpus**
- **IR System**
- **ReRanked Documents**

**Feedback**

- **Revised Query**
- **Query Reformulation**

**Ranked Documents**

Query Reformulation

• Revise query to account for feedback:
  – Query Expansion: Add new terms to query from relevant documents.
  – Term Reweighting: Increase weight of terms in relevant documents and decrease weight of terms in irrelevant documents.

• Several algorithms for query reformulation.
Query Reformulation for VSR

• Change query vector using vector algebra.
• **Add** the vectors for the **relevant** documents to the query vector.
• **Subtract** the vectors for the **irrelevant** docs from the query vector.
• This both adds both positive and negatively weighted terms to the query as well as reweighting the initial terms.
Optimal Query

• Assume that the relevant set of documents \( C_r \) are known.

• Then the best query that ranks all and only the relevant queries at the top is:

\[
\vec{q}_{opt} = \frac{1}{|C_r|} \sum_{\forall \vec{d}_j \in C_r} \vec{d}_j - \frac{1}{N - |C_r|} \sum_{\forall \vec{d}_j \notin C_r} \vec{d}_j
\]

Where \( N \) is the total number of documents.
Standard Rocchio Method

• Since all relevant documents unknown, just use the known relevant \((D_r)\) and irrelevant \((D_n)\) sets of documents and include the initial query \(q\).

\[
\tilde{q}_m = \alpha \tilde{q} + \frac{\beta}{|D_r|} \sum_{\forall \tilde{d}_j \in D_r} \tilde{d}_j - \frac{\gamma}{|D_n|} \sum_{\forall \tilde{d}_j \in D_n} \tilde{d}_j
\]

\(\alpha\): Tunable weight for initial query.
\(\beta\): Tunable weight for relevant documents.
\(\gamma\): Tunable weight for irrelevant documents.
Ide Regular Method

• Since more feedback should perhaps increase the degree of reformulation, do not normalize for amount of feedback:

\[
\tilde{q}_m = \alpha \tilde{q} + \beta \sum_{\forall \tilde{d}_j \in D_r} \tilde{d}_j - \gamma \sum_{\forall \tilde{d}_j \in D_n} \tilde{d}_j
\]

\(\alpha\): Tunable weight for initial query.
\(\beta\): Tunable weight for relevant documents.
\(\gamma\): Tunable weight for irrelevant documents.
Ide “Dec Hi” Method

• Bias towards rejecting just the highest ranked of the irrelevant documents:

\[
\tilde{q}_m = \alpha \tilde{q} + \beta \sum_{\forall \tilde{d}_j \in D_r} \tilde{d}_j - \gamma \max_{\text{non-relevant}} (\tilde{d}_j)
\]

\(\alpha\): Tunable weight for initial query.
\(\beta\): Tunable weight for relevant documents.
\(\gamma\): Tunable weight for irrelevant document.
Comparison of Methods

- Overall, experimental results indicate no clear preference for any one of the specific methods.
- All methods generally improve retrieval performance (recall & precision) with feedback.
- Generally just let tunable constants equal 1.
Evaluating Relevance Feedback

- By construction, reformulated query will rank explicitly-marked relevant documents higher and explicitly-marked irrelevant documents lower.
- Method should not get credit for improvement on these documents, since it was told their relevance.
- In machine learning, this error is called “testing on the training data.”
- Evaluation should focus on generalizing to other un-rated documents.
Fair Evaluation of Relevance Feedback

- Remove from the corpus any documents for which feedback was provided.
- Measure recall/precision performance on the remaining residual collection.
- Compared to complete corpus, specific recall/precision numbers may decrease since relevant documents were removed.
- However, **relative** performance on the residual collection provides fair data on the effectiveness of relevance feedback.
Why is Feedback Not Widely Used

• Users sometimes reluctant to provide explicit feedback.
• Results in long queries that require more computation to retrieve, and search engines process lots of queries and allow little time for each one.
• Makes it harder to understand why a particular document was retrieved.
Pseudo Feedback

- Use relevance feedback methods without explicit user input.
- Just assume the top $m$ retrieved documents are relevant, and use them to reformulate the query.
- Allows for query expansion that includes terms that are correlated with the query terms.

PseudoFeedback Results

• Found to improve performance on TREC competition ad-hoc retrieval task.
• Works even better if top documents must also satisfy additional boolean constraints in order to be used in feedback.
Thesaurus

• A thesaurus provides information on synonyms and semantically related words and phrases.

• Example:

  physician

    syn: ||doc, doctor, MD, medical, mediciner, medico, ||sawbones

    rel: medic, general practitioner, surgeon,
Thesaurus-based Query Expansion

- For each term, $t$, in a query, expand the query with synonyms and related words of $t$ from the thesaurus.
- May weight added terms less than original query terms.
- Generally increases recall.
- May significantly decrease precision, particularly with ambiguous terms.
  - “interest rate” → “interest rate fascinate evaluate”
WordNet

- A more detailed database of semantic relationships between English words.
- Developed by famous cognitive psychologist George Miller and a team at Princeton University.
- About 144,000 English words.
- Nouns, adjectives, verbs, and adverbs grouped into about 109,000 synonym sets called *synsets*.
WordNet Synset Relationships

- **Antonym**: front → back
- **Attribute**: benevolence → good (noun to adjective)
- **Pertainym**: alphabetical → alphabet (adjective to noun)
- **Similar**: unquestioning → absolute
- **Cause**: kill → die
- **Entailment**: breathe → inhale
- **Holonym**: chapter → text (part-of)
- **Meronym**: computer → cpu (whole-of)
- **Hyponym**: tree → plant (specialization)
- **Hypernym**: fruit → apple (generalization)
WordNet Query Expansion

- Add synonyms in the same synset.
- Add hyponyms to add specialized terms.
- Add hypernyms to generalize a query.
- Add other related terms to expand query.
Statistical Thesaurus

- Existing human-developed thesauri are not easily available in all languages.
- Human thesauri are limited in the type and range of synonymy and semantic relations they represent.
- Semantically related terms can be discovered from statistical analysis of corpora.
Automatic Global Analysis

- Determine term similarity through a pre-computed statistical analysis of the complete corpus.
- Compute association matrices which quantify term correlations in terms of how frequently they co-occur.
- Expand queries with statistically most similar terms.
Association Matrix

\[ \begin{pmatrix}
  w_1 & w_2 & w_3 & \ldots & w_n \\
  w_1 & c_{11} & c_{12} & \ldots & c_{1n} \\
  w_2 & c_{21} & \ldots & \ldots \\
  w_3 & c_{31} & \ldots & \ldots \\
  \vdots & \vdots & \ddots & \vdots \\
  w_n & c_{n1} & \ldots & \ldots & \ldots
\end{pmatrix} \]

\( c_{ij} \): Correlation factor between term \( i \) and term \( j \)

\[ c_{ij} = \sum_{d_k \in D} f_{ik} \times f_{jk} \]

\( f_{ik} \): Frequency of term \( i \) in document \( k \)
Normalized Association Matrix

• Frequency based correlation factor favors more frequent terms.

• Normalize association scores:

\[ s_{ij} = \frac{c_{ij}}{c_{ii} + c_{jj} - c_{ij}} \]

• Normalized score is 1 if two terms have the same frequency in all documents.
Metric Correlation Matrix

- Association correlation does not account for the proximity of terms in documents, just co-occurrence frequencies within documents.
- Metric correlations account for term proximity.

\[ c_{ij} = \sum_{k_u \in V_i} \sum_{k_v \in V_j} \frac{1}{r(k_u, k_v)} \]

- \( V_i \): Set of all occurrences of term \( i \) in any document.
- \( r(k_u, k_v) \): Distance in words between word occurrences \( k_u \) and \( k_v \) (\( \infty \) if \( k_u \) and \( k_v \) are occurrences in different documents).
Normalized Metric Correlation Matrix

- Normalize scores to account for term frequencies:

\[
S_{ij} = \frac{c_{ij}}{|V_i| \times |V_j|}
\]
Query Expansion with Correlation Matrix

- For each term $i$ in query, expand query with the $n$ terms, $j$, with the highest value of $c_{ij}$ ($s_{ij}$).
- This adds semantically related terms in the “neighborhood” of the query terms.
Problems with Global Analysis

• Term ambiguity may introduce irrelevant statistically correlated terms.
  – “Apple computer” $\rightarrow$ “Apple red fruit computer”

• Since terms are highly correlated anyway, expansion may not retrieve many additional documents.
Automatic Local Analysis

• At query time, dynamically determine similar terms based on analysis of top-ranked retrieved documents.

• Base correlation analysis on only the “local” set of retrieved documents for a specific query.

• Avoids ambiguity by determining similar (correlated) terms only within relevant documents.
  – “Apple computer” →
    “Apple computer Powerbook laptop”
Global vs. Local Analysis

- Global analysis requires intensive term correlation computation only once at system development time.
- Local analysis requires intensive term correlation computation for every query at run time (although number of terms and documents is less than in global analysis).
- But local analysis gives better results.
Global Analysis Refinements

• Only expand query with terms that are similar to all terms in the query.

$$sim(k_i, Q) = \sum_{k_j \in Q} c_{ij}$$

- “fruit” not added to “Apple computer” since it is far from “computer.”
- “fruit” added to “apple pie” since “fruit” close to both “apple” and “pie.”

• Use more sophisticated term weights (instead of just frequency) when computing term correlations.
Query Expansion Conclusions

- Expansion of queries with related terms can improve performance, particularly recall.
- However, must select similar terms very carefully to avoid problems, such as loss of precision.
