Text Categorization
Categorization

• Given:
  – A description of an instance, $x \in X$, where $X$ is the instance language or instance space.
  – A fixed set of categories: $C = \{c_1, c_2, \ldots, c_n\}$

• Determine:
  – The category of $x$: $c(x) \in C$, where $c(x)$ is a categorization function whose domain is $X$ and whose range is $C$. 
Learning for Categorization

- A training example is an instance \( x \in X \), paired with its correct category \( c(x) \): \( <x, c(x)> \) for an unknown categorization function, \( c \).
- Given a set of training examples, \( D \).
- Find a hypothesized categorization function, \( h(x) \), such that:
  \[
  \forall <x, c(x)> \in D : h(x) = c(x)
  \]
  \textit{Consistency}
Sample Category Learning Problem

• Instance language: \(<\text{size, color, shape}\>\)
  – \(\text{size} \in \{\text{small, medium, large}\}\)
  – \(\text{color} \in \{\text{red, blue, green}\}\)
  – \(\text{shape} \in \{\text{square, circle, triangle}\}\)

• \(C = \{\text{positive, negative}\}\)

• \(D:\)

<table>
<thead>
<tr>
<th>Example</th>
<th>Size</th>
<th>Color</th>
<th>Shape</th>
<th>Category</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>small</td>
<td>red</td>
<td>circle</td>
<td>positive</td>
</tr>
<tr>
<td>2</td>
<td>large</td>
<td>red</td>
<td>circle</td>
<td>positive</td>
</tr>
<tr>
<td>3</td>
<td>small</td>
<td>red</td>
<td>triangle</td>
<td>negative</td>
</tr>
<tr>
<td>4</td>
<td>large</td>
<td>blue</td>
<td>circle</td>
<td>negative</td>
</tr>
</tbody>
</table>
General Learning Issues

• Many hypotheses are usually consistent with the training data.

• Bias
  – Any criteria other than consistency with the training data that is used to select a hypothesis.

• Classification accuracy (% of instances classified correctly).
  – Measured on independent test data.

• Training time (efficiency of training algorithm).
• Testing time (efficiency of subsequent classification).
Generalization

• Hypotheses must generalize to correctly classify instances not in the training data.
• Simply memorizing training examples is a consistent hypothesis that does not generalize.
• *Occam’s razor*:
  – Finding a *simple* hypothesis helps ensure generalization.
Text Categorization

- Assigning documents to a fixed set of categories.

Applications:
- Web pages
  - Recommending
  - Yahoo-like classification
- Newsgroup Messages
  - Recommending
  - spam filtering
- News articles
  - Personalized newspaper
- Email messages
  - Routing
  - Prioritizing
  - Folderizing
  - spam filtering
Learning for Text Categorization

• Manual development of text categorization functions is difficult.

• Learning Algorithms:
  – Bayesian (naïve)
  – Neural network
  – Relevance Feedback (Rocchio)
  – Rule based (Ripper)
  – Nearest Neighbor (case based)
  – Support Vector Machines (SVM)
Using Relevance Feedback (Rocchio)

• Relevance feedback methods can be adapted for text categorization.
• Use standard TF/IDF weighted vectors to represent text documents (normalized by maximum term frequency).
• For each category, compute a prototype vector by summing the vectors of the training documents in the category.
• Assign test documents to the category with the closest prototype vector based on cosine similarity.
Rocchio Text Categorization Algorithm (Training)

Assume the set of categories is \{c_1, c_2, \ldots, c_n\}
For i from 1 to n let \( \mathbf{p}_i = <0, 0, \ldots, 0> \) \ (init. prototype vectors)

For each training example \( <x, c(x)> \in D \)
Let \( \mathbf{d} \) be the frequency normalized TF/IDF term vector for doc \( x \)
Let \( i = j: (c_j = c(x)) \)
\((sum \ all \ the \ document \ vectors \ in \ c_i \ to \ get \ \mathbf{p}_i)\)
Let \( \mathbf{p}_i = \mathbf{p}_i + \mathbf{d} \)
Rocchio Text Categorization Algorithm
(Test)

Given test document $x$
Let $d$ be the TF/IDF weighted term vector for $x$
Let $m = -2$ \textit{(init. maximum cosSim)}
For $i$ from 1 to $n$:
\begin{itemize}
  \item [(compute similarity to prototype vector)]
  \begin{itemize}
    \item Let $s = \text{cosSim}(d, p_i)$
    \item if $s > m$
      \begin{itemize}
        \item let $m = s$
        \item let $r = c_i$ \textit{(update most similar class prototype)}
      \end{itemize}
  \end{itemize}
\end{itemize}
Return class $r$
Illustration of Rocchio Text Categorization
Rocchio Properties

- Does not guarantee a consistent hypothesis.
- Forms a simple generalization of the examples in each class (a prototype).
- Prototype vector does not need to be averaged or otherwise normalized for length since cosine similarity is insensitive to vector length.
- Classification is based on similarity to class prototypes.
**Rocchio Time Complexity**

- **Note:** The time to add two sparse vectors is proportional to minimum number of non-zero entries in the two vectors.

- **Training Time:** $O(|D|(L_d + |V_d|)) = O(|D| L_d)$ where $L_d$ is the average length of a document in $D$ and $V_d$ is the average vocabulary size for a document in $D$.

- **Test Time:** $O(L_t + |C||V_t|)$ where $L_t$ is the average length of a test document and $|V_t|$ is the average vocabulary size for a test document.
  - Assumes lengths of $p_i$ vectors are computed and stored during training, allowing $\text{cosSim}(d, p_i)$ to be computed in time proportional to the number of non-zero entries in $d$ (i.e. $|V_t|$)
Nearest-Neighbor Learning Algorithm

• Learning is just storing the representations of the training examples in $D$.
• Testing instance $x$:
  – Compute similarity between $x$ and all examples in $D$.
  – Assign $x$ the category of the most similar example in $D$.
• Does not explicitly compute a generalization or category prototypes.
• Also called:
  – Case-based
  – Memory-based
  – Lazy learning
K Nearest-Neighbor

• Using only the closest example to determine categorization is subject to errors due to:
  – A single atypical example.
  – Noise (i.e. error) in the category label of a single training example.
• More robust alternative is to find the $k$ most-similar examples and return the majority category of these $k$ examples.
• Value of $k$ is typically odd to avoid ties, 3 and 5 are most common.
Similarity Metrics

- Nearest neighbor method depends on a similarity (or distance) metric.
- Simplest for continuous $m$-dimensional instance space is *Euclidian distance*.
- Simplest for $m$-dimensional binary instance space is *Hamming distance* (number of feature values that differ).
- For text, cosine similarity of TF-IDF weighted vectors is typically most effective.
3 Nearest Neighbor Illustration
(Euclidian Distance)
K Nearest Neighbor for Text

Training:
For each training example \(<x, c(x)> \in D\n
Compute the corresponding TF-IDF vector, \(d_x\), for document \(x\)

Test instance \(y\):
Compute TF-IDF vector \(d\) for document \(y\)
For each \(<x, c(x)> \in D\n
Let \(s_x = \text{cosSim}(d, d_x)\)
Sort examples, \(x\), in \(D\) by decreasing value of \(s_x\)
Let \(N\) be the first \(k\) examples in \(D\). \((\text{get most similar neighbors})\)
Return the majority class of examples in \(N\)
Illustration of 3 Nearest Neighbor for Text
Rocchio Anomaly

- Prototype models have problems with polymorphic (disjunctive) categories.
3 Nearest Neighbor Comparison

- Nearest Neighbor tends to handle polymorphic categories better.
Nearest Neighbor Time Complexity

- **Training Time**: $O(|D| L_d)$ to compose TF-IDF vectors.
- **Testing Time**: $O(L_t + |D||V_t|)$ to compare to all training vectors.
  - Assumes lengths of $d_x$ vectors are computed and stored during training, allowing $\cosSim(d, d_x)$ to be computed in time proportional to the number of non-zero entries in $d$ (i.e. $|V_t|$)

- Testing time can be high for large training sets.
Nearest Neighbor with Inverted Index

- Determining $k$ nearest neighbors is the same as determining the $k$ best retrievals using the test document as a query to a database of training documents.

- **Testing Time**: $O(B|V_t|)$
  
  where $B$ is the average number of training documents in which a test-document word appears.

- Therefore, overall classification is $O(L_t + B|V_t|)$
  
  - Typically $B << |D|$
Bayesian Methods

• Learning and classification methods based on probability theory.
• Bayes theorem plays a critical role in probabilistic learning and classification.
• Uses prior probability of each category given no information about an item.
• Categorization produces a posterior probability distribution over the possible categories given a description of an item.
Axioms of Probability Theory

• All probabilities between 0 and 1

\[ 0 \leq P(A) \leq 1 \]

• True proposition has probability 1, false has probability 0.

\[ P(\text{true}) = 1 \quad P(\text{false}) = 0. \]

• The probability of disjunction is:

\[ P(A \lor B) = P(A) + P(B) - P(A \land B) \]
Conditional Probability

- $P(A \mid B)$ is the probability of $A$ given $B$
- Assumes that $B$ is all and only information known.
- Defined by:

$$P(A \mid B) = \frac{P(A \land B)}{P(B)}$$
Independence

• $A$ and $B$ are *independent* iff:

\[
P(A \mid B) = P(A) \quad \text{These two constraints are logically equivalent} \\
P(B \mid A) = P(B)
\]

• Therefore, if $A$ and $B$ are independent:

\[
P(A \mid B) = \frac{P(A \land B)}{P(B)} = P(A) \\
P(A \land B) = P(A)P(B)
\]
Bayes Theorem

\[ P(H \mid E) = \frac{P(E \mid H)P(H)}{P(E)} \]

Simple proof from definition of conditional probability:

\[ P(H \mid E) = \frac{P(H \wedge E)}{P(E)} \quad \text{(Def. cond. prob.)} \]

\[ P(E \mid H) = \frac{P(H \wedge E)}{P(H)} \quad \text{(Def. cond. prob.)} \]

\[ P(H \wedge E) = P(E \mid H)P(H) \]

**QED:** \[ P(H \mid E) = \frac{P(E \mid H)P(H)}{P(E)} \]
Bayesian Categorization

- Let set of categories be \( \{c_1, c_2, \ldots, c_n\} \)
- Let \( E \) be description of an instance.
- Determine category of \( E \) by determining for each \( c_i \)

\[
P(c_i \mid E) = \frac{P(c_i)P(E \mid c_i)}{P(E)}
\]

- \( P(E) \) can be determined since categories are complete and disjoint.

\[
\sum_{i=1}^{n} P(c_i \mid E) = \sum_{i=1}^{n} \frac{P(c_i)P(E \mid c_i)}{P(E)} = 1
\]

\[
P(E) = \sum_{i=1}^{n} P(c_i)P(E \mid c_i)
\]
Bayesian Categorization (cont.)

• Need to know:
  – Priors: $P(c_i)$
  – Conditionals: $P(E \mid c_i)$

• $P(c_i)$ are easily estimated from data.
  – If $n_i$ of the examples in $D$ are in $c_i$, then $P(c_i) = n_i / |D|$

• Assume instance is a conjunction of binary features:
  $$E = e_1 \land e_2 \land \cdots \land e_m$$

• Too many possible instances (exponential in $m$) to estimate all $P(E \mid c_i)$
Naïve Bayesian Categorization

- If we assume features of an instance are independent given the category \((c_i)\) (conditionally independent).

\[
P(E \mid c_i) = P(e_1 \land e_2 \land \cdots \land e_m \mid c_i) = \prod_{j=1}^{m} P(e_j \mid c_i)
\]

- Therefore, we then only need to know \(P(e_j \mid c_i)\) for each feature and category.
Naïve Bayes Example

• $C = \{\text{allergy, cold, well}\}$
• $e_1 = \text{sneeze}; \ e_2 = \text{cough}; \ e_3 = \text{fever}$
• $E = \{\text{sneeze, cough, } \neg \text{fever}\}$

<table>
<thead>
<tr>
<th>Prob</th>
<th>Well</th>
<th>Cold</th>
<th>Allergy</th>
</tr>
</thead>
<tbody>
<tr>
<td>$P(c_i)$</td>
<td>0.9</td>
<td>0.05</td>
<td>0.05</td>
</tr>
<tr>
<td>$P(\text{sneeze}</td>
<td>c_i)$</td>
<td>0.1</td>
<td>0.9</td>
</tr>
<tr>
<td>$P(\text{cough}</td>
<td>c_i)$</td>
<td>0.1</td>
<td>0.8</td>
</tr>
<tr>
<td>$P(\text{fever}</td>
<td>c_i)$</td>
<td>0.01</td>
<td>0.7</td>
</tr>
</tbody>
</table>
Naïve Bayes Example (cont.)

<table>
<thead>
<tr>
<th>Probability</th>
<th>Well</th>
<th>Cold</th>
<th>Allergy</th>
</tr>
</thead>
<tbody>
<tr>
<td>P($c_i$)</td>
<td>0.9</td>
<td>0.05</td>
<td>0.05</td>
</tr>
<tr>
<td>P(sneeze $</td>
<td>c_i$)</td>
<td>0.1</td>
<td>0.9</td>
</tr>
<tr>
<td>P(cough $</td>
<td>c_i$)</td>
<td>0.1</td>
<td>0.8</td>
</tr>
<tr>
<td>P(fever $</td>
<td>c_i$)</td>
<td>0.01</td>
<td>0.7</td>
</tr>
</tbody>
</table>

\[
P(\text{well} \mid E) = (0.9)(0.1)(0.1)(0.99)/P(E)=0.0089/P(E)
\]
\[
P(\text{cold} \mid E) = (0.05)(0.9)(0.8)(0.3)/P(E)=0.01/P(E)
\]
\[
P(\text{allergy} \mid E) = (0.05)(0.9)(0.7)(0.6)/P(E)=0.019/P(E)
\]

Most probable category: allergy
\[
P(E) = 0.089 + 0.01 + 0.019 = 0.0379
\]
\[
P(\text{well} \mid E) = 0.23
\]
\[
P(\text{cold} \mid E) = 0.26
\]
\[
P(\text{allergy} \mid E) = 0.50
\]

E={sneeze, cough, ¬fever}
Estimating Probabilities

• Normally, probabilities are estimated based on observed frequencies in the training data.
• If $D$ contains $n_i$ examples in category $c_i$, and $n_{ij}$ of these $n_i$ examples contains feature $e_j$, then:

$$P(e_j \mid c_i) = \frac{n_{ij}}{n_i}$$

• However, estimating such probabilities from small training sets is error-prone.
• If due only to chance, a rare feature, $e_k$, is always false in the training data, $\forall c_i : P(e_k \mid c_i) = 0$.
• If $e_k$ then occurs in a test example, $E$, the result is that $\forall c_i: P(E \mid c_i) = 0$ and $\forall c_i: P(c_i \mid E) = 0$
Smoothing

• To account for estimation from small samples, probability estimates are adjusted or *smoothed*.

• Laplace smoothing using an \( m \)-estimate assumes that each feature is given a prior probability, \( p \), that is assumed to have been previously observed in a “virtual” sample of size \( m \).

\[
P(e_j \mid c_i) = \frac{n_{ij} + mp}{n_i + m}
\]

• For binary features, \( p \) is simply assumed to be 0.5.
Naïve Bayes for Text

• Modeled as generating a bag of words for a document in a given category by repeatedly sampling with replacement from a vocabulary $V = \{w_1, w_2, \ldots w_m\}$ based on the probabilities $P(w_j \mid c_i)$.

• Smooth probability estimates with Laplace $m$-estimates assuming a uniform distribution over all words ($p = 1/|V|$) and $m = |V|$:
  - Equivalent to a virtual sample of seeing each word in each category exactly once.
Text Naïve Bayes Algorithm
(Train)

Let \( V \) be the vocabulary of all words in the documents in \( D \)
For each category \( c_i \in C \)
   Let \( D_i \) be the subset of documents in \( D \) in category \( c_i \)
   \[ P(c_i) = \frac{|D_i|}{|D|} \]
Let \( T_i \) be the concatenation of all the documents in \( D_i \)
Let \( n_i \) be the total number of word occurrences in \( T_i \)
For each word \( w_j \in V \)
   Let \( n_{ij} \) be the number of occurrences of \( w_j \) in \( T_i \)
   Let \( P(w_i \mid c_i) = \frac{n_{ij} + 1}{n_i + |V|} \)
Text Naïve Bayes Algorithm (Test)

Given a test document $X$
Let $n$ be the number of word occurrences in $X$
Return the category:

$$\arg\max_{c_i \in C} P(c_i) \prod_{i=1}^{n} P(a_i | c_i)$$

where $a_i$ is the word occurring the $i$th position in $X$
Naïve Bayes Time Complexity

- **Training Time:** $O(|D|L_d + |C||V|))$
  - Assumes $V$ and all $D_i$, $n_i$, and $n_{ij}$ pre-computed in $O(|D|L_d)$ time during one pass through all of the data.
  - Generally just $O(|D|L_d)$ since usually $|C||V| < |D|L_d$

- **Test Time:** $O(|C| L_t)$
  - $L_t$ is the average length of a test document.

- Very efficient overall, linearly proportional to the time needed to just read in all the data.
- Similar to Rocchio time complexity.
Underflow Prevention

- Multiplying lots of probabilities, which are between 0 and 1 by definition, can result in floating-point underflow.
- Since $\log(xy) = \log(x) + \log(y)$, it is better to perform all computations by summing logs of probabilities rather than multiplying probabilities.
- Class with highest final un-normalized log probability score is still the most probable.
Naïve Bayes Posterior Probabilities

- Classification results of naïve Bayes (the class with maximum posterior probability) are usually fairly accurate.
- However, due to the inadequacy of the conditional independence assumption, the actual posterior-probability numerical estimates are not.
  - Output probabilities are generally very close to 0 or 1.
Evaluating Categorization

- Evaluation must be done on test data that are independent of the training data (usually a disjoint set of instances).

- *Classification accuracy*: $c/n$ where $n$ is the total number of test instances and $c$ is the number of test instances correctly classified by the system.

- Results can vary based on sampling error due to different training and test sets.

- Average results over multiple training and test sets (splits of the overall data) for the best results.
$N$-Fold Cross-Validation

- Ideally, test and training sets are independent on each trial.
  - But this would require too much labeled data.
- Partition data into $N$ equal-sized disjoint segments.
- Run $N$ trials, each time using a different segment of the data for testing, and training on the remaining $N-1$ segments.
- This way, at least test-sets are independent.
- Report average classification accuracy over the $N$ trials.
- Typically, $N = 10$. 
Learning Curves

• In practice, labeled data is usually rare and expensive.

• Would like to know how performance varies with the number of training instances.

• *Learning curves* plot classification accuracy on independent test data (*Y axis*) versus number of training examples (*X axis*).
N-Fold Learning Curves

• Want learning curves averaged over multiple trials.
• Use $N$-fold cross validation to generate $N$ full training and test sets.
• For each trial, train on increasing fractions of the training set, measuring accuracy on the test data for each point on the desired learning curve.
