IN-CLASS WORK: TRAFFIC FLOW

At the beginning of class I will guide us through the program for the initialization of the road, including task 4a.

~kvollmay/share.dir/inclass2025.dir/traffic4aonly.py

And I will describe what you want to achieve in task 4b.

4. Distance

4a. Next we work on finding the distance between a car and the car in front of it. To get this distance we will avoid in the following to have to check each site in front of a car if it is empty or not. Instead we define an additional array: carpos which stores for each car on the road its position on the road. So if the first car (index 0) on the road is on site 3 then carpos[0]=3, if the second car is on site 5 then carpos[1]=5, etc.. Add to your program of 3. the array carpos, initialize carpos in the same loop when you initialize the road array, and check your program by printing out both the complete road and the carpos array.

4b. Now add to your program (after the initialization of road and carpos) a loop over cars on the street to determine (and print out) for each car the distance to the car in front of it. Take into accout the periodic boundary conditions both to determine the car in front and to determine the distance.

Comment: This task is more difficult than it might seem at first glance. I comment on this in my intro words.

5. Update Velocities

5a. For the update of the velocities we will need a function which determines the smallest number of three integers. Python has a function which does this, for example $\min(3,1,9)$ gives 1 as result. Test this function with a few print commands

5b. Add to the program that it determines all new velocities (and updates them in the road array), and prints out the road with the new velocities. Check your program with print commands.

6. Update Positions

Now you are ready to add to your program the update of the positions. To do so use a new loop over all cars and update both the carpos array and the road array. For the update of road make sure to first copy the new velocity into a variable (e.g. vnew), then empty the old site and then put the car in road on its new site xnew = xold + vnew with the new velocity (the order of these commands matters). Remember to use the periodic boundary condition. After the update of all positions print the complete road and check if it is what you expected.

7. Finish Program (if time)

Now you are set to finish the program for our traffic flow model. Add to your program from 6. the time loop. Print your road for the case of 15 timesteps (MAXTIMESTEPS = 15), PCAR=0.3, and similarly the other parameters the same as in traffic4.py.
