# The Purpose of Networking

- Goal: Allow computers to communicate (exchange data and/or commands).
- A few desirable properties:
  - Interoperability,
  - Flexibility,
  - Geographical range,
  - Scalability,
  - Privacy and security.

### Matters of Protocol

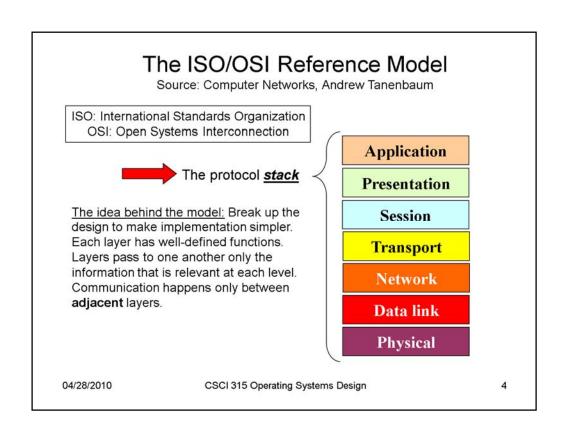

#### Everything in networking happens through *protocols*:

- A protocol determines how hosts share and access the medium,
- ► A protocol determines how hosts deal with the media bandwidth, errors, flow control, etc,
- ▶ A protocol determines how connections between hosts are established and maintained,
- ▶ A protocol determines how information is routed across short and long distances, etc, etc, etc...

Question: Ok, but what is protocol?

CSCI 315 Operating Systems Design

### The Layers in the ISO/OSI RF Model

Physical: Transmit raw bits over the medium.

<u>Data Link:</u> Implements the abstraction of an error free medium (handle losses, duplication, errors, flow control).

Network: Routing.

<u>Transport:</u> Break up data into chunks, send them down the protocol stack, receive chunks, put them in the right order, pass them up.

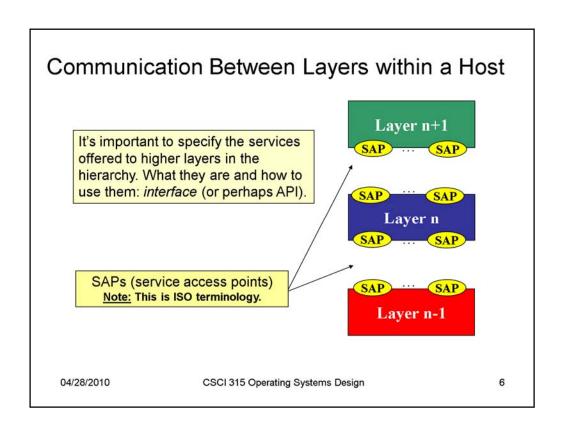

<u>Session:</u> Establish connections between different users and different hosts.

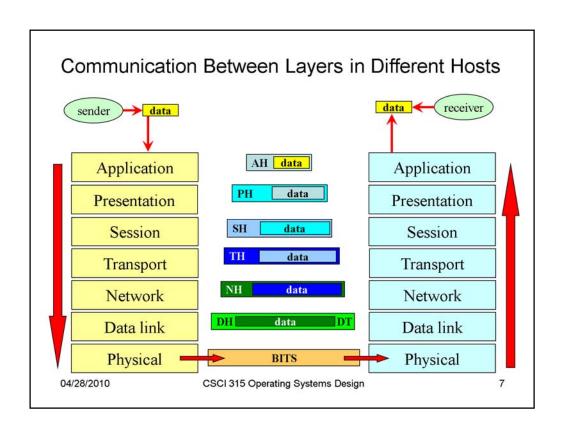

<u>Presentation:</u> Handle syntax and semantics of the info; examples: encoding, encrypting.

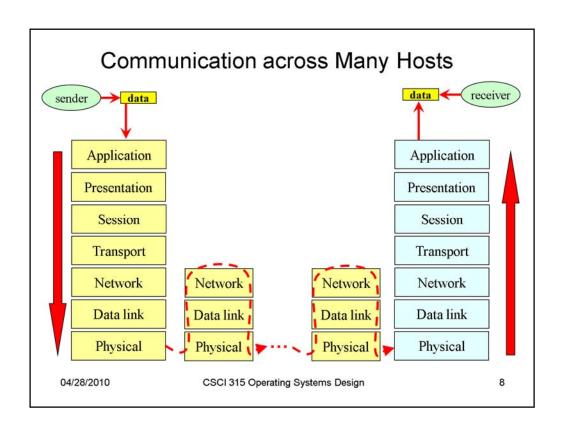

<u>Application:</u> Protocols commonly needed by applications (cddb, http, ftp, telnet, etc).

# **Network Topology**

We can classify computer networks according to their topology:

### Range of Coverage

We can also classify computer networks according to their geographical coverage:

LAN: local area network

WLAN: wireless local area network

MAN: metropolitan area network

WAN: wide area network (long haul network)

Most commonly, we're interested in the seamless integration of all these levels (as in the Internet).

Note: Different levels use very different technologies.

### **Technology**

Network Interface Card (NIC): I/O device in the computer system that allows it to join a network.

The NIC works with a specific medium (twisted-pair, coaxial cable, optic fiber, etc).

As long as its bus allows, a host can have multiple NICs.

To the host, the NIC is just another I/O device, which has its own address (known as MAC address, set by the manufacturer). A *protocol* determines how the NIC accesses the medium.
